Weathering an Unexpected Financial Shock: The Role of Cash Grants on Household Finance and Business Survival

Justin Gallagher, Daniel Hartley, and Shawn Rohlin*

December 11, 2020

*E-mail: *justin.gallagher1@montana.edu*, *daniel.a.hartley@chi.frb.org*, *srohlin@kent.edu* The authors would like to thank seminar participants at Case Western Reserve University, Federal Reserve Bank of Chicago, Federal Reserve System Committee on Regional Analysis, Georgia State University, London School of Economics, Louisiana State University, Ohio State University, UNLV, University of Wisconsin, Wharton and at the American Economic Association, Association of Environmental and Resource Economists, and the Urban Economics Association meetings. A special thanks to Benjamin Collier, Scott Shane, John Stevens, and Alejandro Del Valle for feedback. Jacqueline Blair, Simin Gao, Benjamin Marks, Sarah Mattson, Kyle Musser, and Jacob Rabin provided outstanding research assistance. Gallagher thanks the Freedman Center for Digital Scholarship and the Initiative for Regulation and Applied Economic Analysis for research support. The opinions expressed are those of the authors and do not necessarily represent the views of the Federal Reserve Bank of Chicago or the Board of Governors of the Federal Reserve System.

Contents

1 Data Appendix

1.1 Tornado Sample

As discussed in Section 2.1 of the main text, the tornado sample includes 34 individual tornadoes. All tornadoes in the sample have a Fujita (F) or Enhanced Fujita (EF) rating of a 4 or 5, and a map demarcating heterogeneous intensities within the tornado path. We use the Tornado History Project database (www.tornadohistoryproject.com) to form this sample. We restrict to the years 2002-2013, so as to match the period covered by our individual and business data. The Tornado History Project obtains data from the Storm Prediction Center's (SPC) historical tornado data files (www.spc.noaa.gov/wcm/#data). These data are maintained by the SPC, the National Centers for Environmental Protection, and the National Weather Service (NWS). The Tornado History Project reports 15,247 individual tornadoes from 2002-2013. Restricting to tornadoes with a F/EF rating rating of a 4 or 5 results in 87 tornadoes.

We further restrict tornadoes in the sample to have a detailed map denoting heterogeneous intensities within the tornado path. To our knowledge, there is no single database that contains damage maps for all tornadoes in the US. To locate the detailed maps we conducted an extensive search within local NWS office websites, and using more general web-based and archival searches. The search was conducted from from June 2013-August 2014.

The key feature of the NWS maps is that they are damage maps created by trained NWS employees who survey the on-the-ground damage. For example, the following link provides details on the May 22, 2011 Joplin, MO tornado: https://www.weather.gov/sgf/news_events_2011may22. The NWS has developed extensive manuals and computer software that relate observable damage to an EF rating. The first step involves documenting the severity of a damaged structure (e.g. detached house, mobile home, tree). The training manuals emphasize paying close attention to both a structure's materials and design, as well as, the state-level building codes. The NWS uses engineering models that relate the type of structure, the observed damage, and the underlying building codes to the range of wind speeds that would most-likely have caused the damage (Edwards et al. [2013]).

The US National Oceanic and Atmospheric Administration (NOAA) provides the following details to the questions "Who surveys tornado damage?" and "What's the criteria for the National Weather Service to do a survey?":

"This varies from place to place; and there are no rigid criteria. The responsibility for damage survey decisions at each NWS office usually falls on the Warning-Coordination Meteorologist (WCM) and/or the Meteorologist in Charge (MIC). Budget constraints keep every tornado path from having a direct ground survey by NWS personnel; so spotter, chaser and news accounts may be used to rate relatively weak, remote or brief tornadoes. Killer tornadoes, those striking densely populated areas, or those generating reports of exceptional damage are given highest priority for ground surveys. Most ground surveys involve the WCM and/or forecasters not having shift responsibility the day of the survey. For outbreaks and unusually destructive events–usually only a few times a year–the NWS may support involvement by highly experienced damage survey experts and wind engineers from elsewhere in the country. Aerial surveys are expensive and usually reserved for tornado events with multiple casualties and/or massive degrees of damage. Sometimes, local NWS offices may have a cooperative agreement with local media or police to use their helicopters during surveys."

Source: https://www.spc.noaa.gov/faq/tornado/index.html#Damage

We include a tornado map in our sample if it contains exact locations of where the tornado hit at various F/EF intensities, and also have sufficient detail that it can be georeferenced using GIS software (ESRI ArcMap). We were able to obtain detailed damage maps for 35 of the 87 F/EF tornadoes. Many of the tornadoes for which we could not locate detailed maps occurred in very rural locations and directly hit few, if any, homes or built structures. It is likely that detailed maps were not created for these tornadoes. Regardless, we would not be able to include most of these tornadoes in our sample because there would be insufficient credit bureau or business establishment data (in the Federal Reserve Bank of New York Consumer Credit Panel / Equifax (CCP) and Infogroup's Historical Business Database, respectively).

Appendix Table 1 lists each of the 35 tornadoes. The table includes the date and location (closest city) of each tornado, and the following statistics provided by the Tornado History Project: fatalities, injuries, and estimated damage. The table also indicates whether each tornado was part of a Presidential Disaster Declaration, whether Public Assistance or Individual Assistance (cash grants) was allocated, and if the tornado is included in our balanced 18 tornado robustness sample.

Our main sample includes 34 tornadoes. We exclude one tornado from the sample (the Wayne, NE tornado in Appendix Table 1). The Wayne, NE tornado has differing pre-tornado trends for the hit and nearby businesses (see Appendix Figure 3). The differing pre-trends violate our key difference-in-differences and triple-difference modeling assumption. Moreover, the difference for this tornado is large enough to alter the pre-trends for the entire group of no-cash tornadoes (see Appendix Figure 4). We drop the Wayne, NE tornado from both the business and household finance samples, so as to conduct our main analysis on the same sample of tornadoes.

1.2 GIS Data Processing

1.2.1 Tornado Maps

The goal of the GIS data processing is to use the detailed tornado maps to determine the list of census blocks that are hit by the tornado and the list of census blocks that are just outside the tornado path and located in the 0.5-1.5 mile buffer region. Further, we calculate the percent of each block that incurs each level of F/EF damage in the tornado path. We use the percent of each block hit by the various F/EF damage levels to calculate a weighted damage intensity for every hit block. We also calculate the fraction of the block that is in the buffer region. We only include blocks in our nearby control sample if more than 50% is located in the buffer region. This restriction, along with the half mile gap between the tornado path and our buffer region, helps to ensure that no portion of a nearby control block is also hit by the tornado.

The first step in the GIS process is to georeference the exact location of the tornado path. Occasionally, the tornado maps are available as GIS shapefiles which, after projecting the shapefiles, provide the exact tornado location. More often, we georeference the tornado path location ourselves by adding a US highway/major/minor roads layer within the GIS software (ESRI ArcMap) on top of the tornado damage heterogeneity map. Geographic points are identified on the heterogeneous damage map such as intersections of highways and major/minor roads. The damage maps are then georeferenced by lining up the identified points on the map image with the same points on the US highway/major/minor roads layer.

Next, we calculate the portion of each block (if any) that incurs each level of tornado damage, and the proportion of each block (if any) that falls inside the buffer region. We

do this by intersecting the 2000 US Census block shapefile corresponding to the state (or states) hit by each tornado with the georeferenced tornado map. We calculate a block-level weighted intensity measure for each block. The block-level intensity measure is defined as the sum: (0 * %EF0) + (1*%EF1) + ... + (5 * %EF5). Not all tornadoes have each damage level. Occasionally, the tornado maps will indicate EF0 damage, whereby the block is clearly located in the tornado path, but there is only minimal damage.

Finally, the block-level tornado information is exported to a .csv datafile. The exported GIS-calculated tornado information is then matched on census block fips number to the household finance and business datasets.

1.2.2 Appendix Figure 1 and Table 2

Appendix Figure 1 and Appendix Table 3 both use ZIP Code level FEMA Individual Assistance (cash grant) and SBA disaster loan data. We use the detailed georeferenced tornado damage maps discussed in Appendix Section 1.2.1 to obtain the list of "hit" and "buffer" ZIP Codes. To do this, we overlay state-specific 2000 US Census TIGER/Line ZIP Code shapefiles onto each tornado map using Arc GIS. A hit ZIP Code is defined as one which intersects with any portion of the tornado path. For example, in Appendix Figure 1, the following ZIP Codes are hit: 64801, 64804, 64840, 64844. A buffer ZIP Code is one that intersects with the 0.5 to 1.5 mile buffer zone outside of the tornado path and does not intersect with the tornado path. In Appendix Figure 1, ZIP Codes 64841 and 64862 are buffer ZIP Codes. If a ZIP Code is within the buffer zone and the tornado path, we define it as hit.

Note that the ZIP Code definition for hit is different than the one we use for the block-level analysis in the paper. Census blocks are geographically much smaller than ZIP Codes. This allows us to have stricter definitions for hit and buffer areas in the empirical analysis. In the analysis, a hit block is one that is at least 50% in the tornado path, while a buffer (control) block is one that is at least 50% in the buffer zone.

1.3 Data Sources

This section lists information on all the data sources used in the paper. Further details provided in the paper. We list each source here for completeness.

1.3.1 Federal Emergency Management Agency (FEMA)

The Federal Emergency Management Agency (FEMA) is the source of the Presidential Disaster Declaration, Public Assistance, and Individual Assistance data. The FEMA website (https://www.fema.gov/disasters) provides information on whether there is a Presidential Disaster Declaration following the storm that includes each tornado, and whether Public Assistance and Individual Assistance (cash grants) disaster aid is distributed. The publicly available information on the website is typically provided at the disaster-level (and occasionally the county-level).

The Individual Assistance data we use are from a Freedom of Information Act Request (FOIA). We submitted a FOIA (No. 2015-FEFO-00159) in December 2014 for block-level Individual Assistance information. We received the FOIA information in January 2019. However, due to confidentiality considerations, FEMA provided 5-digit ZIP Code level information (rather than block-level). The information includes: disaster declaration number, ZIP Code, earliest application approval date, total number of housing grants, total amount of housing assistance, total number of other needs assistance (ONA) grants, and total amount of ONA. The information was provided for 23 of the 25 tornadoes in our full sample that are part of Presidential Disaster Declarations with Individual Assistance. We do not have ZIP Code level cash grant information for the 2008 Waterloo, Iowa and 2008 Ridgeville, Georgia tornadoes. We are happy to share all of the FOIA Individual Assistance data.

1.3.2 Federal Reserve Bank of New York Consumer Credit Panel / Equifax (CCP)

The credit and debt information is from the Federal Reserve Bank of New York Consumer Credit Panel / Equifax (CCP). The consumer credit panel was first created via a collaboration between researchers at the Federal Reserve Bank of New York and Equifax, a credit repository company. The panel is updated quarterly. Lee and van der Klaauw [2010] provide a comprehensive summary of the information included in the CCP. We are not able to post or share these data due to confidentiality concerns and a strict user agreement.

The CCP data include a quarterly foreclosure variable that indicates whether an individual had a foreclosure in the past seven years. We do not use this variable to examine how offering cash assistance following a tornado affects quarterly foreclosure rates. The reason is

due to a combination of three factors: our sample size, the fact that new quarterly foreclosures are very uncommon, and that we need to use an inexact proxy to identify changes in foreclosure.

Overall, the fraction of our sample that has the foreclosure flag equal to one in the quarter before a tornado ranges from 0.017 to 0.022 across the hit and nearby groups (Manuscript Table 1). To measure the rate of new foreclosures we calculate the quarterly change in this foreclosure flag. We proxy the quarterly foreclosure rate as quarterly changes in the fraction of individuals with the foreclosure flag equal to one. This proxy is inexact because it will not reflect a new foreclosure if an individual had a foreclosure within the past seven years. Perhaps more problematic, is that the proxy will be partly driven by foreclosures that occurred seven years ago dropping off an individual's credit report.

Appendix Figure 2 shows our measure of quarterly foreclosure rates for the four groups in our sample relative to when a tornado hit. The average foreclosure rate is approximately 0.002 across the groups and is an order of magnitude smaller than the (seven year) sample means in Manuscript Table 1. Moreover, the foreclosure rate proxy is zero for at least one quarter for each of the four groups, and equal to zero for the majority of quarters for the hit group without access to cash assistance. Overall, we interpret Appendix Figure 2 as evidence that we do not have enough power to estimate changes in foreclosures using the seven year foreclosure flag in our setting.

1.3.3 Infogroup's Historic Business Database

We use business establishment data from the Infogroup's Historic Business Database. An independent audit by the College of Information Science & Technology at the University of Nebraska at Omaha found the database similar to, and on many dimensions, of higher quality than other private establishment-level datasets such as the National Establishment Time-Series dataset (College of Information Science & Technology at the University of Nebraska [2017]). We are not able to post or share these data due to a strict user agreement.

1.3.4 National Weather Service (NWS)

The tornado maps are created by the National Weather Service. To our knowledge, there is no single location that includes all of the NWS maps with sub-tornado path F/EF ratings.

We collected the tornado maps used in this study over the time period June 2013-August 2014 via archival and internet searches. We are happy to share all of the NWS geocoded map data.

1.3.5 Small Business Administration (SBA)

Annual Small Business Administration disaster loan data are publicly available at the 5 digit ZIP Code level separately for home and business loans. We downloaded the data directly from the SBA website https://www.sba.gov/offices/headquarters/oda/resources/1407821 (FY 2001-2013). The SBA information includes dollar amounts for: real estate loss, content loss, real estate loans, content loans, and (for businesses) economic injury loans.

1.3.6 Tornado History Project

The Tornado History Project, http://www.tornadohistoryproject.com, is a searchable database that archives all reported US tornadoes from 1950-2017. The underlying source of the tornado information is the Storm Prediction Center's (SPC) historical tornado data file (https://www.spc.noaa.gov/wcm/#data). The Storm Prediction Center is part of the National Weather Service and the National Centers for Environmental Prediction. Tornado cost, casualty, and maximum intensity information are from the Tornado History Project.

1.3.7 US Decennial Census

We use two sources of data from the US Census. First, are the demographic and socioeconomic information from the 2000 decennial census. These data are used as part of a pre-tornado comparison between hit and nearby populations. Second, are 2000 decennial census block shapefiles. We use the shapefiles in the GIS data processing.

1.3.8 Voting Information

We collect county level vote share data from uselectionatlas.org. For each PDD county, we calculate the average share of the two party (Democratic and Republican) vote that the losing party receives across the 1996, 2000, and 2004 presidential elections.

2 Cost per Job Calculation

Manuscript Section 5 follows Brown and Earle [2017] and calculates a rough measure for the cost per created or retained job. We use the following equation to calculate the cost:

$$Cost\ Per\ Job\ =\ \frac{Total\ IA\ Costs}{Total\ Jobs\ Created} \tag{1}$$

2.1 Total Jobs Created

Total Jobs Created (denominator of Appendix Equation 1) is estimated from our log and level employment results for establishments that have three or fewer employees.[1] The estimated employment gains are then multiplied by the total number of employees in the year before a tornado to determine the number of jobs created by the cash grants. We use total employment at establishments with three or fewer employees located in blocks that are hit by a cash tornado the following year as the baseline level of employment. We estimate that 963 jobs were created.

2.2 Cost Per Job

2.2.1 Baseline Calculation

Our baseline cost per job calculation only considers direct IA program costs. We define direct IA program costs as the sum of the total IA grant dollars and the total FEMA administrative costs related to running the IA program.

We calculate total IA grant dollars by summing the amount of Individual Assistance allocated for the entire Presidential Disaster Declaration area in Manuscript Table 8 panel A. We restrict the calculation to ZIP Codes hit by a tornado in Manuscript Table 8 panel B. The amount of cash assistance to hit ZIP Codes still overstates cash assistance to the damaged tornado blocks.

We calculate total FEMA administrative costs using a Government Accountability Office (GAO) report on FEMA's state-level obligations for major disasters declared during fiscal years 2004 through 2013 (GAO [2014], Table 8). We first estimate the amount of FEMA

[1] Manuscript Table 6 panel C, column 2, estimates the block-level cash grant employment effect for small establishments.

administrative overhead for every IA dollar. The numerator in Equation 2 is an estimate of the total FEMA administrative expense to run the IA program for each state. The total expenditure categories include Public Assistance, Individual Assistance, Mission Assignment, and Hazard Mitigation. We divide these IA-related administrative costs by the total IA dollars in the state to obtain a state-by-state administrative cost per IA grant dollar.

$$Admin\ Dollar\ Per\ IA\ Dollar = \frac{Admin\ Costs * (\frac{IA}{TotalExpenditures})}{IA} \tag{2}$$

Each state's administrative cost per IA grant dollar is then multiplied by the state's total amount of IA grant dollars. For example, if a state allocated $10 million in IA grants and we estimate that it costs $0.2 dollars in administrative overhead for every $1 IA dollar spent, then we would estimate a total administrative cost of $2 million for that state.

The baseline total Individual Assistance program costs for our sample is $233.28 million. We divide the baseline IA cost by our jobs estimate to obtain our baseline cost per job (Manuscript Table 8, Panel A, Column 1) .

2.2.2 More Comprehensive Calculations

Manuscript Table 8 columns 2-5 provide rough estimates of the net job cost inclusive of other program costs and fiscal externalities (e.g. Bastian and Jones [2019]; Hendren [2016]).

Manuscript Table 8 column 2 considers administrative cost savings from issuing fewer SBA disaster loans. FEMA is prohibited from duplicating benefits between the Individual Assistance and SBA programs (SBA [2011]). We assume that in the absence of the cash grants that an equal dollar amount of SBA disaster loans would have been distributed to disaster victims. Using Brown and Earle [2017] (pages 1074-1075) we calculate that recipients default on roughly 8% of SBA loan dollars (18.9 billion out of 230 billion). Therefore, for each IA grant dollar distributed, we estimate a cost savings of $0.08 due to foregone defaults under the SBA program. These administrative cost savings are subtracted from our baseline total costs when calculating the cost per job.

Manuscript Table 8 column 3 considers federal tax revenue raised from the additional jobs. We use two primary data sources to estimate the additional tax revenue. The first data source are state level salary estimates for each state and year in our sample from the Bureau of Labor Statistics Quarterly Census of Employment and Wages (Bureau of Labor Statistics

[2019]). Specifically, we use the "average annual pay" for the "Total, all industries" group. Second, we use the National Bureau of Economic Research (NBER) income tax calculator for "US Federal Marginal Income Tax Rates: Tax Rate on Wage Income" (National Bureau of Economic Research [2019]). We use these two data sources to calculate the average federal tax an employee would pay (i.e. federal taxes per employee per year). We sum the estimated federal tax revenue across states and years. We use the number of employees at small establishments in cash-tornado hit blocks for each state in the year before the tornado as the state-by-year specific level of employment. The total federal tax revenue is subtracted from our baseline total costs when calculating the cost per job.

Manuscript Table 8 column 4 considers federal cost savings from lower unemployment benefits due to fewer unemployed workers. Evidence in the Manuscript suggests that the difference between cash and no-cash disaster blocks is largely due to "retained" jobs rather than "new" jobs. Thus, the cash grants mostly aid in preventing job loss. Unemployment insurance benefits are paid by states. The federal government typically pays only for the administrative costs of running the unemployment insurance programs up to 26 weeks (Stone and Chen [2014]). The federal government can extend unemployment benefits beyond 26 weeks. We do not factor any extended federal unemployment benefits into our calculation. The total estimated federal costs to administer the unemployment insurance program is subtracted from our baseline total costs when calculating the cost per job. Here are the steps we use to calculate the cost savings from reduced unemployment benefits:

(1) We calculate the average length of unemployment from 2002-2013 as 25.54 weeks using data from the Federal Reserve (FED [2019]).

(2) We use an estimate for the cost in administration overhead per-person, per-week for the federal government to run the unemployment program (Whittaker et al. [2019], page 1). Using the FY2020 proposed budget, the document states that for every 100,000 person increase in average weekly claims above the baseline amount, $28.6 million in funding would be available. We use this statistic to calculate an administrative cost of $286 allocated per person per week (i.e. $28,600,000 / 100,000 more weekly claims).

(3) Our estimate for the total unemployment savings to the federal government is: Total Jobs Created * 25.54 weeks * $286

Manuscript Table 8 column 5 presents cost per job estimates when cost savings from columns 2-4 are added together and then subtracted from our baseline total costs.

3 Supporting Analysis

3.1 Main Samples

This section provides supporting analysis for the main household finance and business establishment samples that include 34 tornadoes. The tables and figures in this section are all directly referenced in the manuscript.

Appendix Figure 1 shows the total amount of Individual Assistance cash grants received for each ZIP Code in the vicinity of the May 22, 2011 Joplin, MO tornado. The majority of the tornado path and nearly all of the most highly damaged areas occur in a single ZIP Code (64804). More than $12 million is provided to residents in this ZIP Code. Nevertheless, the tornado only hits 9.95% of the land area of the ZIP Code. Some residents in portions of the ZIP Code farther away from the tornado path likely experienced minor storm-related damage and receive cash assistance. As evidence for this, all of the ZIP Codes surrounding the tornado path have non-zero levels of cash assistance. The majority of these ZIP Codes (colored light blue in the figure) receive much smaller levels of total cash grants, ranging from $408 to $301,382. This figure is referenced in manuscript Section 2.2.

Appendix Figure 2 plots quarter to quarter changes in the foreclosure rate, as proxied by the fraction of each group with the seven year foreclosure flag equal to one. The four groups are individuals hit and nearby to Cash and No-cash tornadoes, respectively. The vertical line indicates the last quarter before a tornado. Sources: Federal Reserve Bank of New York Consumer Credit Panel / Equifax (CCP), National Weather Service, US Census. Foreclosure is referenced in manuscript Section 4.1.2.

Appendix Figure 3 plots the trends in the number of establishments and employment in blocks hit by and nearby to a tornado. The difference between this figure and Manuscript Figure 5 is that the no-cash tornado trends are plotted only for the Wayne, NE tornado. The Wayne, NE tornado is omitted from the main 34 tornado sample due to divergent pre-tornado business trends. This figure is referenced in manuscript Section 3.

Appendix Figure 4 shows the trends in the number of establishments and employees for

establishments located in hit Census blocks at the time of a tornado, and for establishments near to, but outside the tornado path. The difference between this figure and Manuscript Figure 5 is that the no-cash tornado trends include hit and control blocks from the Wayne, NE tornado. This figure is referenced in manuscript Section 3.

Appendix Figure 5 shows the distribution of establishments by employment size for the 34 tornado sample analyzed in Manuscript Table 6. This figure is referenced in manuscript Section 4.2.2.

Appendix Table 1 shows summary information for all 35 tornadoes in our full sample. The 35 tornadoes are the subset of the 87 Fujita or Enhanced Fujita 4 and 5 tornadoes that struck the US between 2002-2013 which have detailed damage path maps. Manuscript Section 2.1 and Appendix Section 1.1 provide more details.

Appendix Table 2 provides summary information for the tornadoes in our main sample. These results are referenced in manuscript Section 2.2.

Appendix Table 3 shows summary statistics for the level of SBA disaster loans awarded to the hit and nearby ZIP Codes following a tornado. SBA disaster loans are available to both individuals (households) and businesses. Individuals can apply for up to $240 thousand, while businesses can apply for up to $2 million (SBA [2018]). Loan amounts are based on verified losses (i.e. building damage, personal property, business property). Small businesses can also receive loans based on "economic injury" (e.g. documented income loss). Loan applicants do not need collateral, but must demonstrate credit worthiness. Not all applications are approved. The total verified losses are higher for loan applicants in areas hit by cash assistance tornadoes. However, the average amount of approved loans is lower for cash assistance tornadoes (e.g. $1.32 million vs. $1.41 million for home loans). One explanation is that, by law, the amount of SBA disaster loans allocated are reduced dollar for dollar based on the receipt of IA cash grants (SBA [2011]). By contrast, the total verified business loss and total approved business loans are both higher for establishments hit by tornadoes with cash assistance. This table is referenced in manuscript Section 2.2.

Appendix Tables 4-6 show difference-in-differences estimates for individual debt, financial distress, and migration using the CCP. We separately estimate the model for cash and no-cash tornadoes for each dependent variable. These tables are referenced in manuscript Section 4.1.

Appendix Table 7 shows difference-in-difference model results for home debt conditional on whether an individual affected by a tornado (either hit or nearby) moved or stayed in

the same census block following the tornado, and by type of home debt. Columns 1-2 only include individuals who move (for at least one quarter) at any point during the three years following the tornado. Columns 3-4 only include individuals who do not move. Our main measure of home debt includes both mortgage debt and home equity debt. Columns 5-6 only consider mortgage debt, while columns 7-8 only consider home equity debt. This table is referenced in manuscript Section 4.1.1.

Appendix Tables 8 and 9 show triple difference estimates for establishments in each of the "1 digit" industries that we pool together in the non-manufacturing category (Manuscript Table 6). These tables are referenced in manuscript Section 4.2.2.

Appendix Tables 10 shows our regression estimates for the number and dollar amount of new auto loan originations, and for retail and establishment sales. These results are referenced in Section 4.2.3. Note that, unlike our other CCP dollar debt variables, we do not winsorize at the 99% level. The reason is that the new dollar loan variable is a flow variable with a median of $0. A decision to winsorize would affect a large fraction of the non-zero values. Nevertheless, the regression results are similar regardless of the decision to winsorize.

3.2 Robustness

Appendix Tables 11-21 show robustness analysis for the household finance and migration outcomes (Manuscript Tables 2 - 4), and for the business outcomes (Manuscript Tables 5 and 6). We estimate two alternative specifications for each outcome. First, we show results from the balanced tornado sample, selected to minimize the difference in the CCP debt and financial variables for individuals hit by cash and no-cash tornadoes. Second, we estimate the model on the full sample that includes the Wayne, NE tornado that is dropped from our preferred sample due to differing pre-trends. These results are referenced throughout the manuscript including Sections 3, 4.1.5, and 4.2.4.

Appendix Figures 6-9 show event study household finance and migration outcomes for the two alternative specifications.

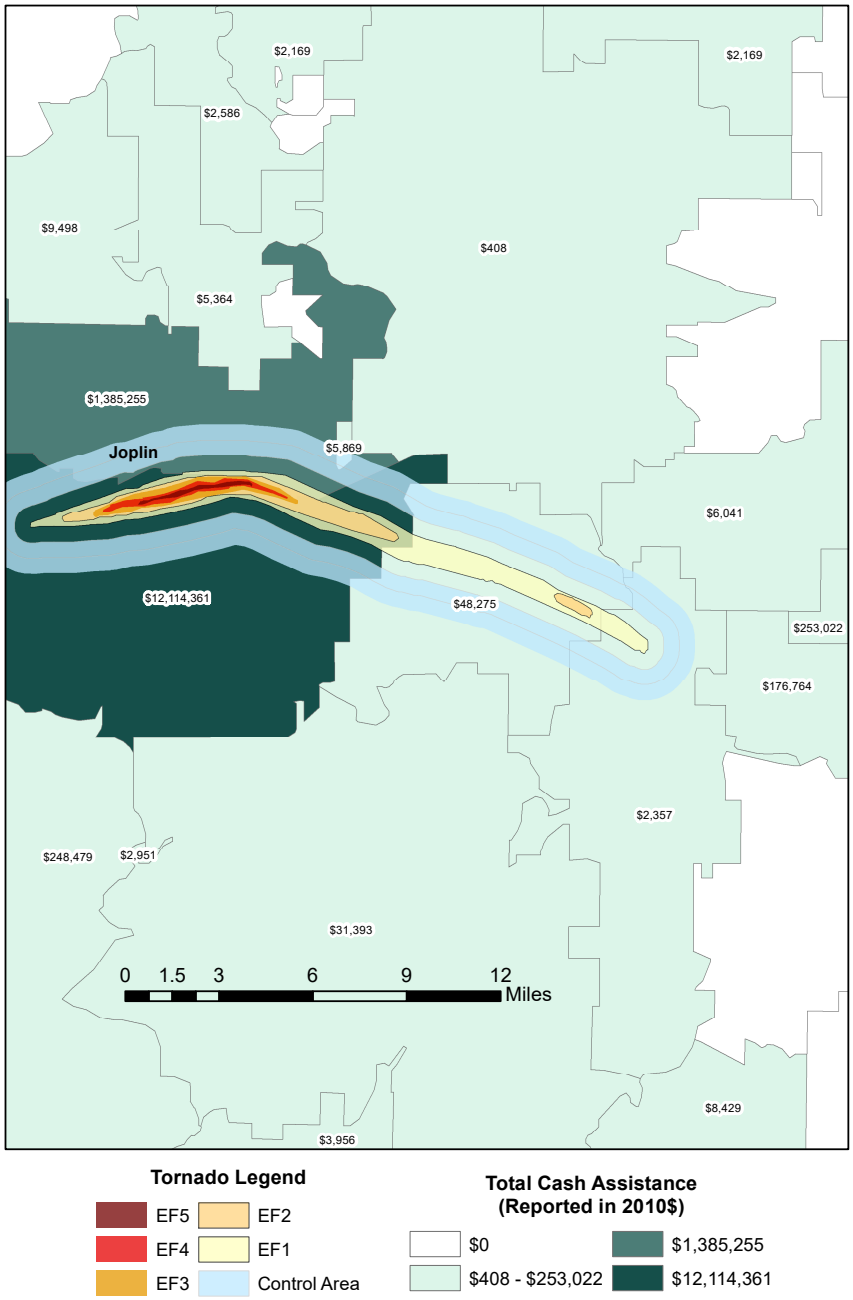
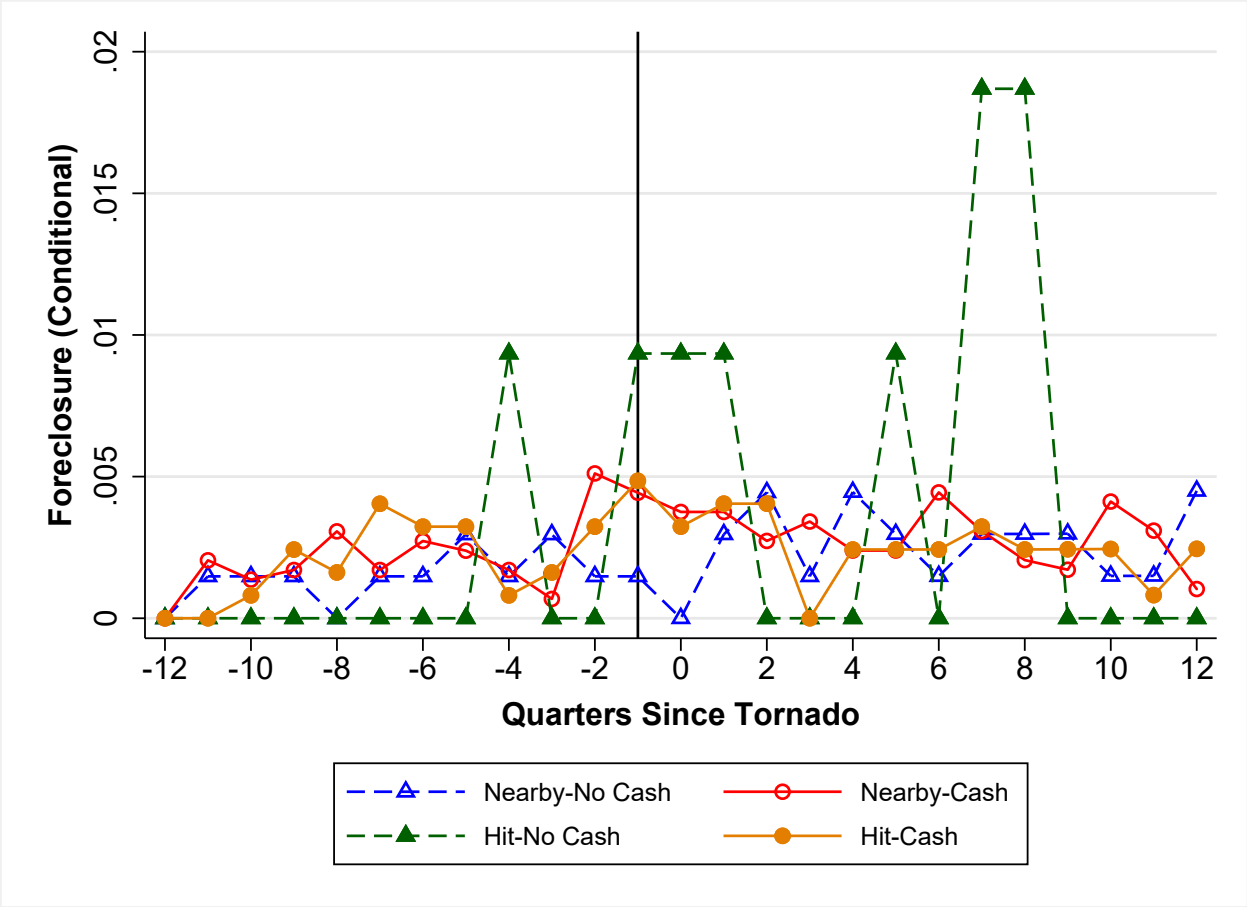
5 Figures and Tables

Figure 1: **Individual Assistance Cash Grants for the Presidential Disaster Declaration that includes the Joplin, MO 2011 Tornado**



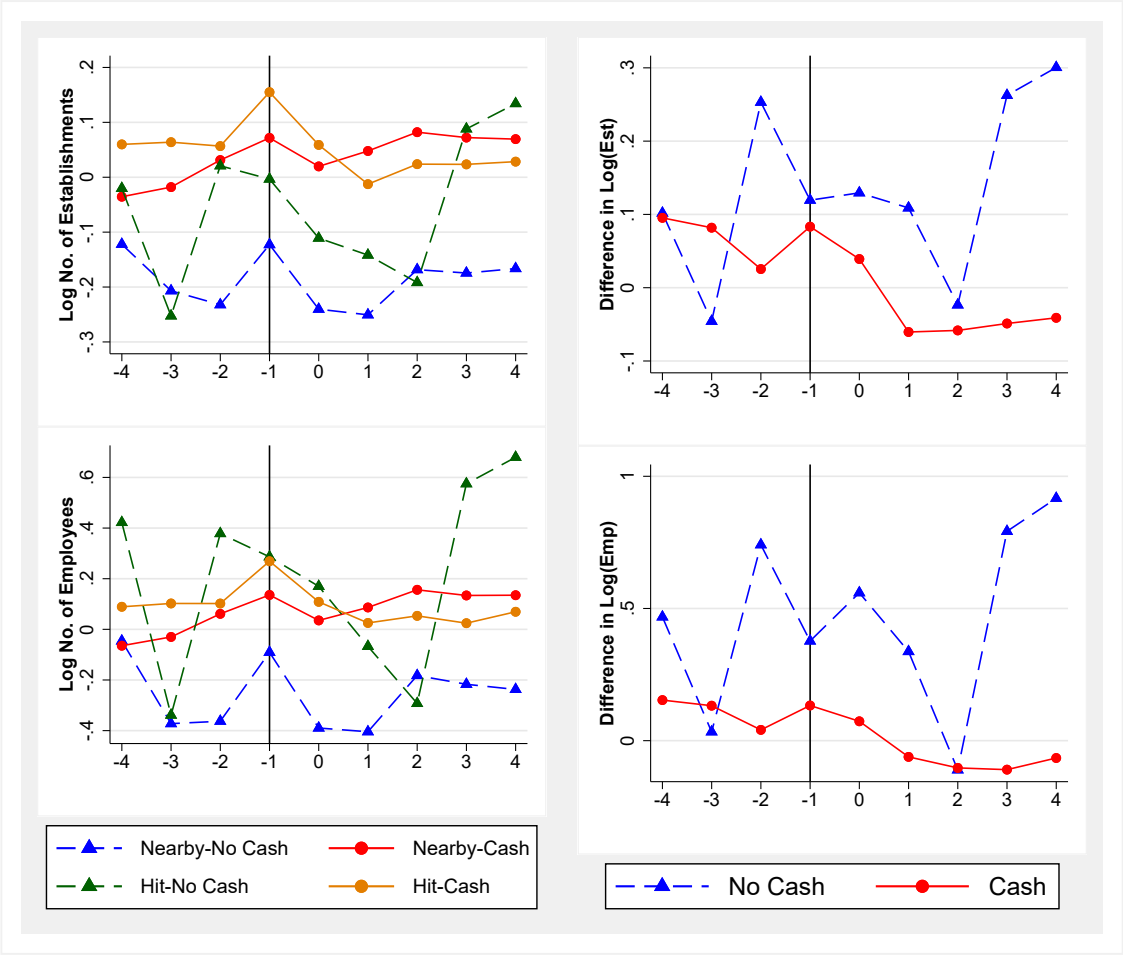
The figure plots the tornado path and 0.5-1.5 tornado buffer region for the EF5 tornado that struck near Joplin, MO on May 22, 2011. The figure also displays the total amount of Individual Assistance cash grants received for each ZIP Code. The Individual Assistance data are from a Freedom of Information Act Request (No. 2015-FEFO-00159) submitted in December 2014 and received in January 2019. Due to confidentiality considerations, FEMA provided 5-digit ZIP Code level information (rather than block-level). Sources: Federal Emergency Management Agency, National Weather Service, US Census.

Figure 2: **Trends in New Foreclosures**



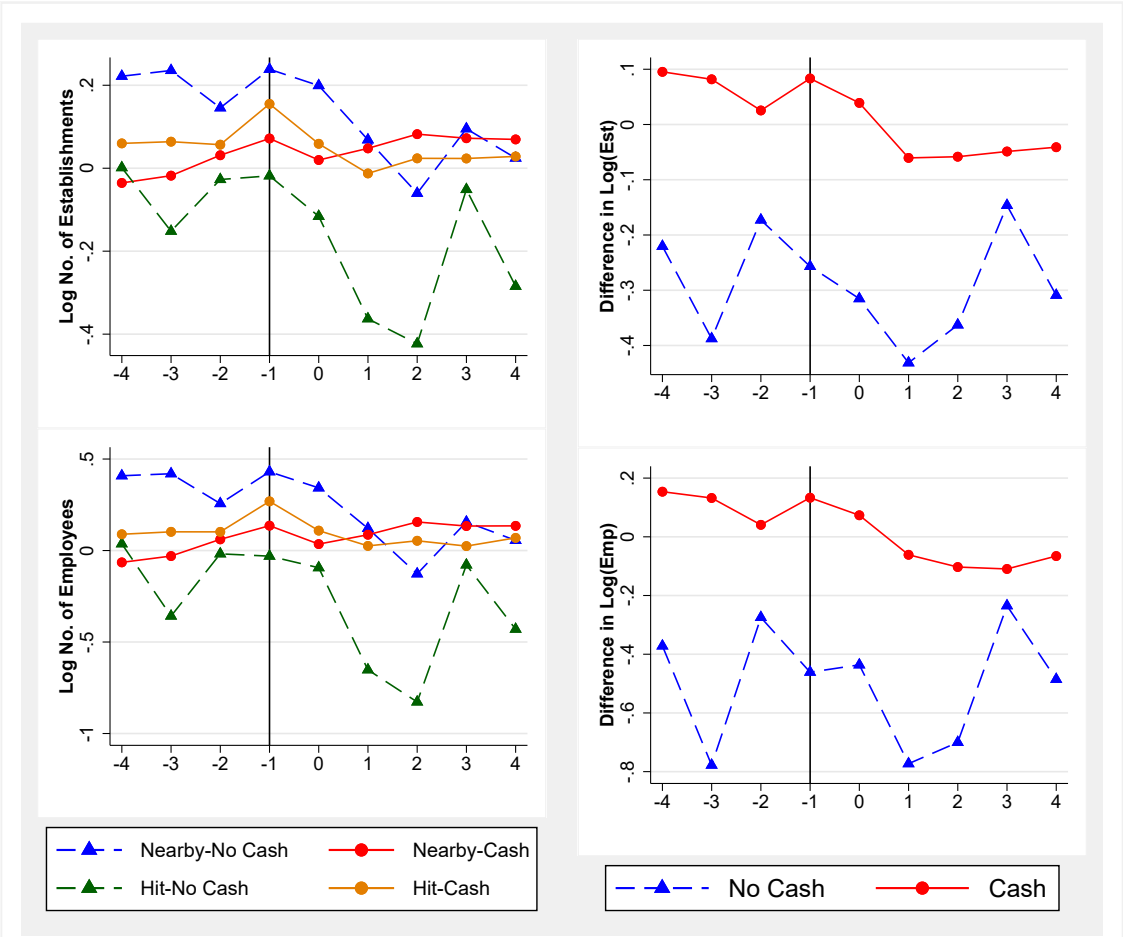
The figure plots quarter to quarter changes in the foreclosure rate, as proxied by the faction of each group with the seven year foreclosure flag equal to one. The four groups are: non-hit residents who lived in the 0.5 to 1.5 mile buffer area around the tornadoes that did not receive cash grants (dashed blue triangles), hit residents who lived in the damage path of tornadoes that did not receive cash grants (dashed green triangles), non-hit residents who lived in in the buffer areas of the tornadoes that did receive cash grants (solid red circles), and hit residents from tornadoes that received cash grants (solid orange circles). The vertical line indicates the last quarter before a tornado. Sources: Federal Reserve Bank of New York Consumer Credit Panel / Equifax (CCP), National Weather Service, US Census.

Figure 3: **Trends in Business Outcomes for the Sample of Cash Tornadoes and the No-cash Wayne, NE Tornado Excluded from the Main Sample**



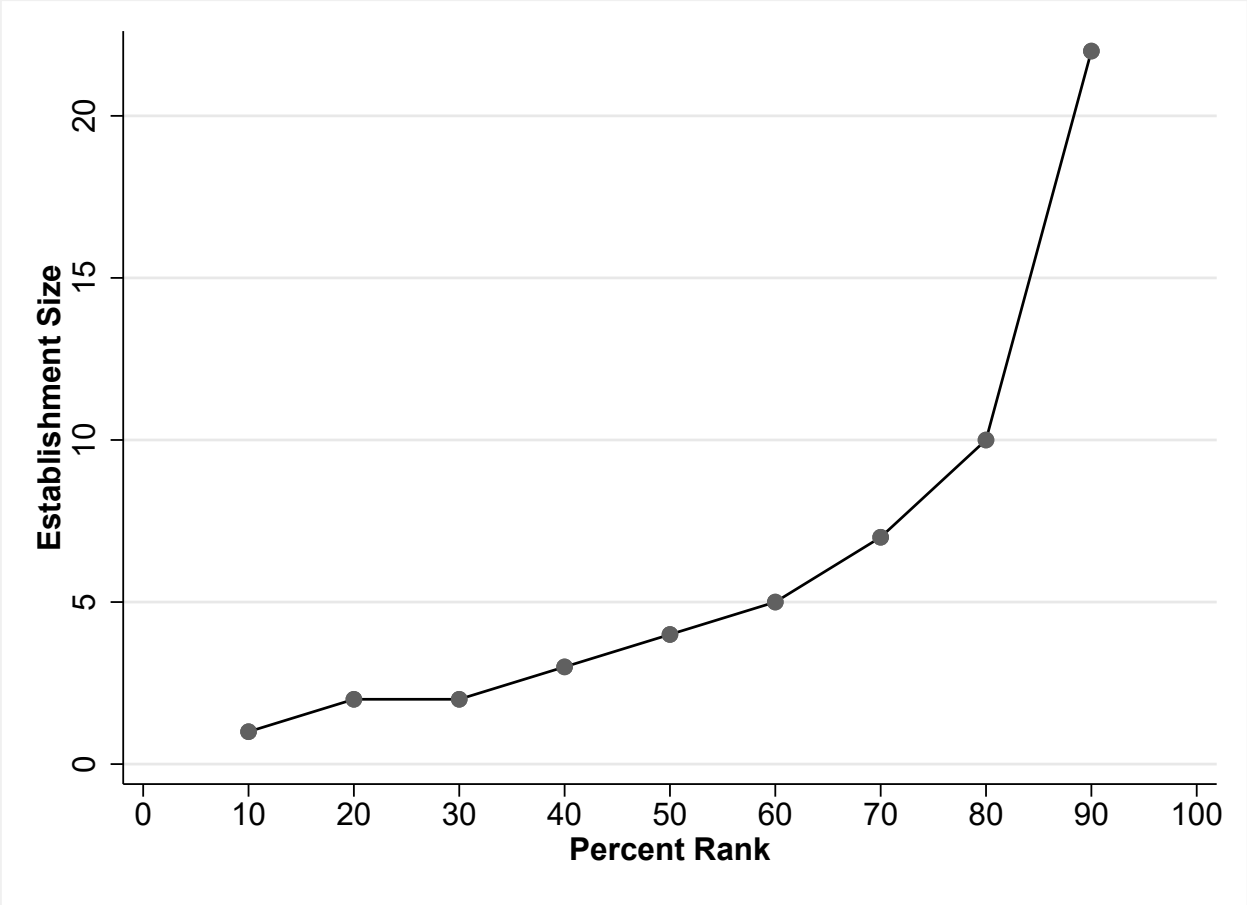
The figure shows the trends in the number of establishments and employees for establishments located in hit Census blocks at the time of a tornado, and for establishments near to, but outside the tornado path. The difference between this figure and Manuscript Figure 5 is that the no-cash tornado trends are plotted only for the Wayne, NE tornado. The Wayne, NE tornado is omitted from the main sample. The cash tornado observations are identical to those plotted in Manuscript Figure 5. Manuscript Section 4.2 provides more details. Sources: Infogroup Historic Business Database, National Weather Service, US Census.

Figure 4: **Trends in Business Outcomes, 35 Tornado Sample Including the Wayne, NE Tornado**



The figure shows the trends in the number of establishments and employees for establishments located in hit Census blocks at the time of a tornado, and for establishments near to, but outside the tornado path. The difference between this figure and Manuscript Figure 5 is that the no-cash tornado trends include hit and control blocks from the Wayne, NE tornado. Manuscript Section 4.2 provides more details. Sources: Infogroup Historic Business Database, National Weather Service, US Census.

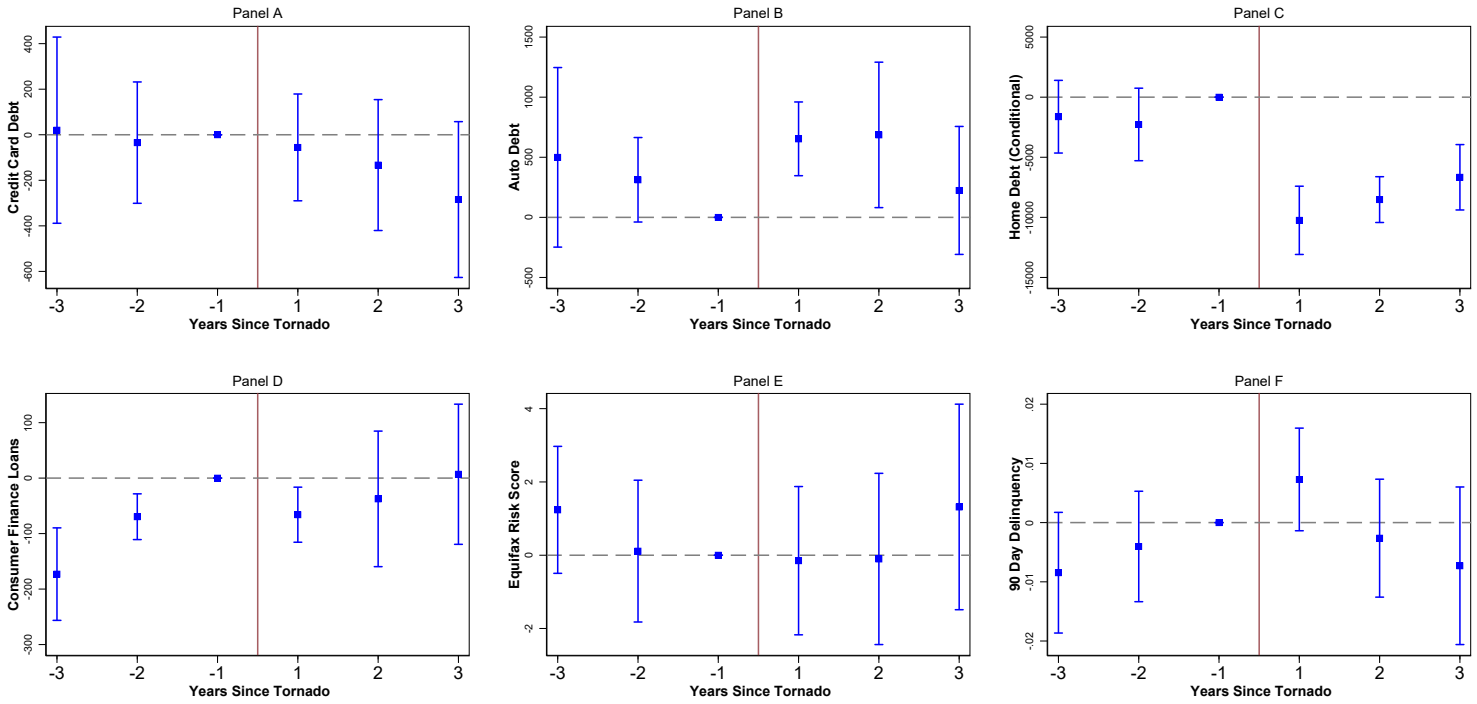
Figure 5: **Distribution of Establishment Size by Number of Employees**



This figure shows the distribution of establishments by employment size for the 34 tornado sample analyzed in Manuscript Table 6. Sources: Infogroup Historical Database, National Weather Service

Figure 6: **Yearly Event Study Analysis of Debt, Financial Wellbeing, and Migration**

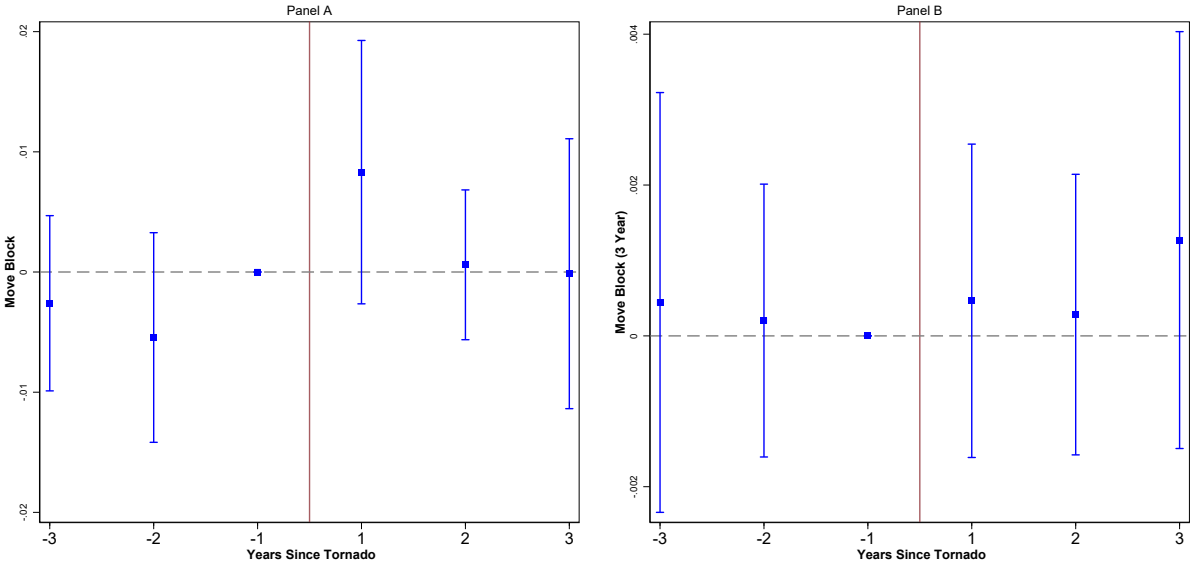
18 Tornado Balanced Sample



The figure shows yearly event study estimates and 95% confidence intervals for the outcomes in Manuscript Figure 3. The difference is that this figure shows results from an event study model that uses the 18 tornado balanced sample. Sources: Federal Reserve Bank of New York Consumer Credit Panel / Equifax (CCP), National Weather Service, US Census.

Figure 7: **Yearly Event Study Analysis of Block Migration**

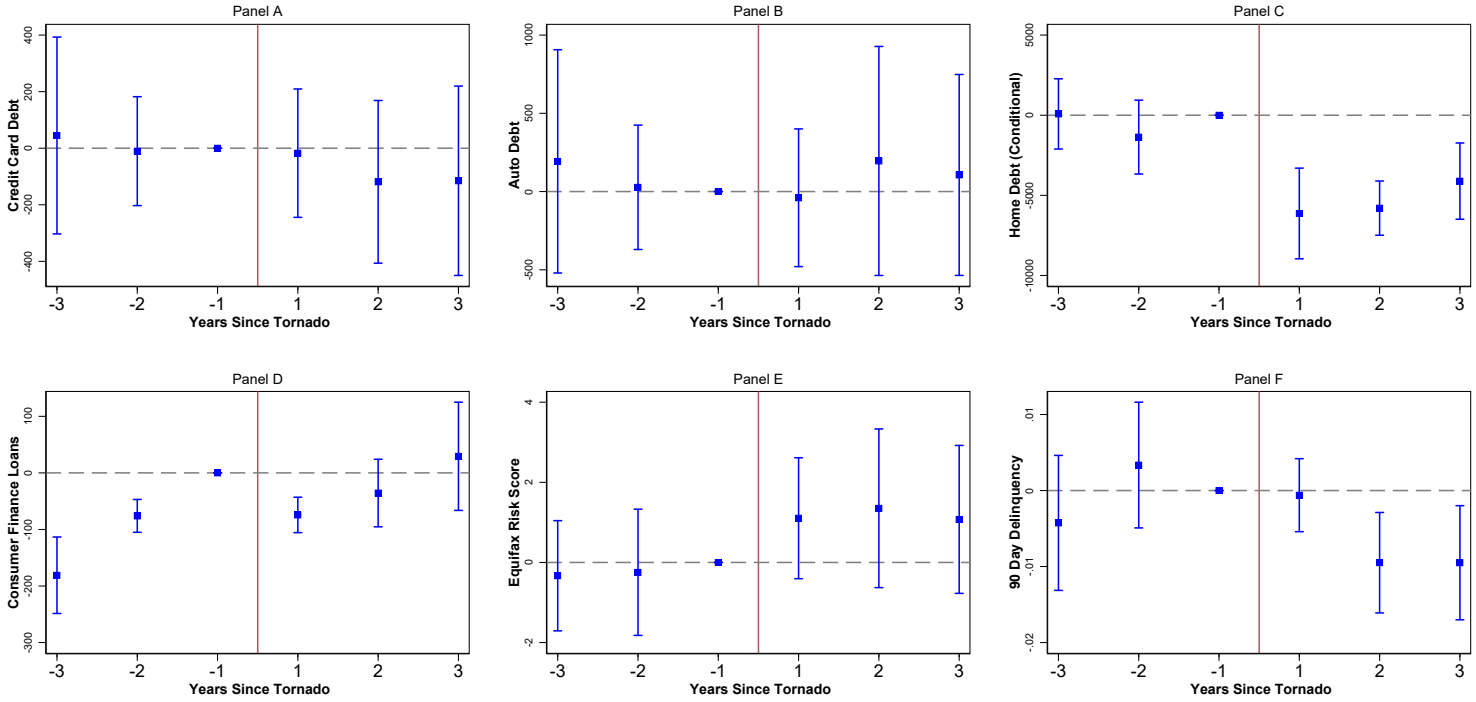
18 Tornado Balanced Sample



The figure shows yearly event study estimates and 95% confidence intervals for the same migration outcomes as in Manuscript Figure 4. The difference is that this figure shows results from an event study model that uses the 18 tornado balanced sample. Sources: Federal Reserve Bank of New York Consumer Credit Panel / Equifax (CCP), National Weather Service, US Census.

Figure 8: **Yearly Event Study Analysis of Debt, Financial Wellbeing, and Migration**

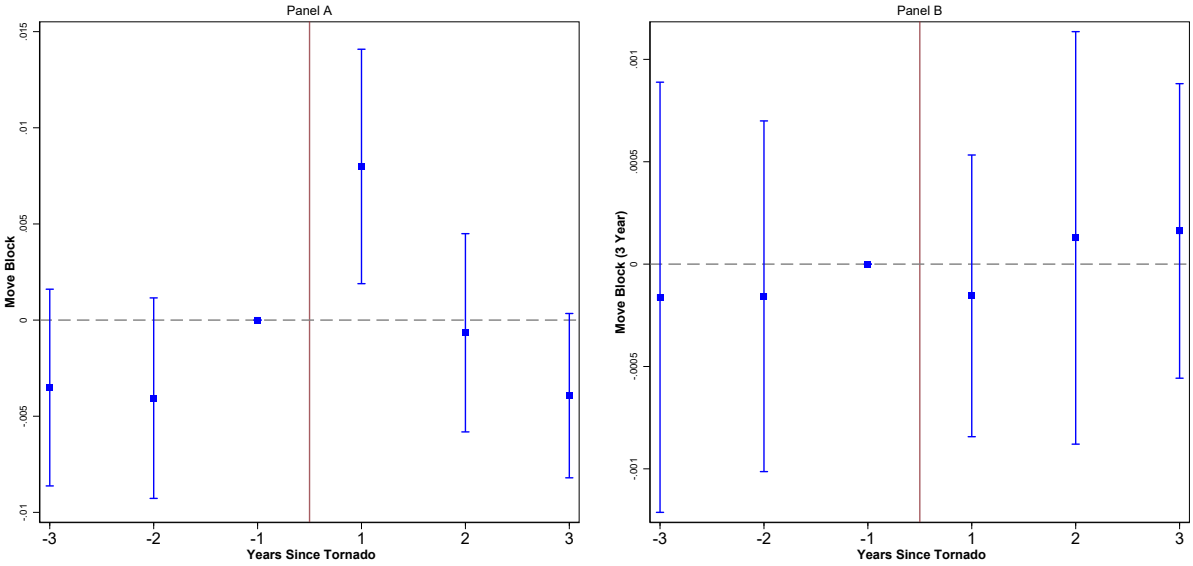
35 Tornado Sample



The figure shows yearly event study estimates and 95% confidence intervals for the outcomes in Manuscript Figure 3. The difference is that this figure shows results from estimating the event study model on the sample of 35 tornadoes that includes the Wayne, NE tornado. Sources: Federal Reserve Bank of New York Consumer Credit Panel / Equifax (CCP), National Weather Service, US Census.

Figure 9: **Yearly Event Study Analysis of Block Migration**

35 Tornado Sample



The figure shows yearly event study estimates and 95% confidence intervals for the same migration outcomes as in Manuscript Figure 4. The difference is that this figure shows results from estimating the event study model on the sample of 35 tornadoes that includes the Wayne, NE tornado. Sources: Federal Reserve Bank of New York Consumer Credit Panel / Equifax (CCP), National Weather Service, US Census.

Table 1: **Location, Damage, and Federal Assistance Information for All 35 Tornadoes**

Date of Tornado	Nearby City	Tornado F/EF	Fatalities	Injuries	Casualties	Estimated Damage (Millions)	Presidential Disaster Declaration	Public Assistance	Individual Assistance	Included In Balanced Sample

11/17/2013	New Minden, IL	4	2	2	4	---	Y	N	Y	Y

The table shows summary information for all 35 tornadoes in our full sample. The 35 tornadoes are the subset of the 87 Fujuti or Enhanced Fujita 4 and 5 tornadoes that struck the US between 2002-2013 which have detailed damage path maps. The Ferguson, MP tornado crosses the state line. A portion of the tornado is in Illinois where individuals did not receive cash assistance. Manuscript Section 2.1 and Appendix Section 1.1 provide more details. Sources: Tornado History Project, National Weather Service, Small Business Administration, US Census.

Table 2: **Tornado Damage Characteristics**

Panel A: Overall Sample Characteristics	
Total Number of Tornadoes	34
Individual Assistance (Cash Grants)	25
Tornado Damage Severity	
F5/EF5 Tornadoes	7
F4/EF4 Tornadoes	27
States hit by Tornado	15

Panel B: Characteristics by Assistance Status

	Cash Assistance Mean (Median)	No Cash Assistance Mean (Median)
Disaster-Level		
Number of Counties in Disaster Declaration	34.8 (23)	7.1 (0)
Percent State Counties in Disaster Declaration	42.8 (29)	6.8 (0)
Electoral Competitiveness of State	42.6 (41.9)	43.9 (44.1)
Tornado-Level		
Tornado F/EF Rating	4.3 (4)	4.0 (4)
Number of Damaged Blocks	381 (233)	58 (45)
Estimated Tornado Damage (Millions $)	513 (150)	53 (40)
Fatalities	19 (8)	2 (1)
Casualties	178 (59)	23 (13)
Block-Level		
Average Block F/EF Rating	1.39 (1.44)	0.84 (0.70)
Average Tornado Damage per Block (Millions $)	1.43 (0.60)	1.25 (0.48)

Tornadoes occur from 2002-2013. Damages in 2010$. *Electoral Competitiveness* follows Reeves [2011] and measures the 2-way voteshare of the losing political party at the midpoint of our sample (2007) averaged over 3 presidential elections (2004, 2000, and 1996). Sources: Federal Emergency Management Agency, Tornado History Project, US Census, uselectionatlas.org

Table 3: **Small Business Administration Loans Summary Statistics**

Hit ZIP Code Statistic:	Mean (Median)	Mean(Median)
Panel A: Cash versus No Cash Tornadoes		
	Cash Tornado	**No Cash Tornado**
Home Loans		
Total Verified Loss (1,000 $)	4,211 (701)	3,051 (170)
Total Approved Loans (1,000 $)	1,321 (266)	1,414 (132)
Per-Capita Approved Loans	297 (37)	344 (12)
Business Loans		
Total Verified Loss (1,000 $)	1,886 (68)	1,567 (0)
Total Approved Loans (1,000 $)	490 (0)	436 (0)
Per-Establishment Approved Loans ($)	3,138 (0)	2,394 (0)
Panel B: High versus Low Tornado Damage		
	F3 or Greater	**Less than F3**
Home Loans		
Total Verified Loss (1,000 $)	8,913 (3170)	1,042 (212)
Total Approved Loans (1,000 $)	2,807 (1014)	409 (80)
Per-Capita Approved Loans	649 (132)	85 (18)
Business Loans		
Total Verified Loss (1,000 $)	4,048 (352)	483 (20)
Total Approved Loans (1,000 $)	1008 (28)	163 (0)
Per-Establishment Approved Loans ($)	5,895 (300)	1,373 (0)

The SBA loan data are discussed in Manuscript Section 2.2 of the Manuscript. Sources: National Weather Service, Small Business Administration, US Census.

This table presents difference-in-difference (DD) estimates for the four consumer debt outcomes we analyze using a triple difference model in the Manuscript (Table 2, columns 1-4). The DD estimates represent the pre- to post-tornado difference in debt outcomes for hit individuals as compared to non-hit individuals in the 1-mile tornado buffer region. The table displays DD estimates separately for cash and no-cash tornadoes. Standard errors (in parentheses) are robust to heteroskedasticity and clustered by tornado. Sources: Federal Reserve Bank of New York Consumer Credit Panel / Equifax (CCP), National Weather Service, US Census.

Table 5: **Household Finance Difference-in-Differences Estimates for Financial Health**

Columns 1-2 only include individuals who move (for at least one quarter) at any point during the three years following the tornado. Columns 3-4 only include individuals who do not move. Columns 5-6 only consider mortgage debt, while columns 7-8 only consider home equity debt. Standard errors (in parentheses) are robust to heteroskedasticity and clustered by tornado. Sources: Federal Reserve Bank of New York Consumer Credit Panel / Equifax (CCP), National Weather Service, US Census.

The table shows triple difference estimates for new car loans, new car loan balances, and retail and service establishment sales. The model includes individual and quarter fixed effects. Only the triple difference coefficients of interest are reported. The pooled coefficients in panel A consider a block as hit if more than 50% of the block is inside the tornado path. The binned coefficients in panel B are estimated separately for individuals in blocks with low (F/EF < 1), medium (F/EF ≥ 1 & < 3), and high (F/EF ≥ 3) damage. Dependent variable means are for the last quarter before a tornado. We do not winsorize the new auto loan variable at the 99% level. The reason is that the new dollar loan variable is a flow variable with a median of $0. A decision to winsorize would affect a large fraction of the non-zero values. Standard errors (in parentheses) are robust to heteroskedasticity and clustered by tornado. Sources: Federal Reserve Bank of New York Consumer Credit Panel / Equifax (CCP), Infogroup Historic Business Database, National Weather Service, US Census.

The table shows triple difference estimates for whether an individual hit by a tornado moves from their census block or county. Columns (1) and (2) define a move as being for (at least) one quarter, while columns (3) and (4) define a move as being for (at least) three years. The sample and econometric models underlying the estimates in this table are the same as those for Manuscript Table 3, except that the sample in this table is the 18 Tornado Balanced Sample. Standard errors (in parentheses) are robust to heteroskedasticity and clustered by tornado. Sources: Federal Reserve Bank of New York Consumer Credit Panel / Equifax (CCP), National Weather Service, US Census.

Observations	766,357	766,357	766,357	766,357

The table shows triple difference estimates for whether an individual hit by a tornado moves from their census block or county. Columns (1) and (2) define a move as being for (at least) one quarter, while columns (3) and (4) define a move as being for (at least) three years. The sample and econometric models underlying the estimates in this table are the same as those for Manuscript Table 3, except that the sample in this table is the 35 tornado sample that includes the Wayne, NE tornado. Standard errors (in parentheses) are robust to heteroskedasticity and clustered by tornado. Sources: Federal Reserve Bank of New York Consumer Credit Panel / Equifax (CCP), National Weather Service, US Census.
